# Insight Cart- AI Powered Retail Sales Intelligent System

**Pardeep[1], Arya[2], Jaydeep Sahoo[3]**
[1]Assistant Professor [2,3], Research Scholar,
Cse Department, Hmritm Ggsipu, Delhi-110036

**Abstract- Artificial Intelligence (AI) & Data Analytics have had a huge impact on the retail sector. This project will develop a web-based retail sales intelligence system with AI capabilities. The AI will help analyze sales data, monitor inventory sales and understand customer behavior for business insight.The system will provide various KPIs, revenue trends, inventory levels and item sales. The system will help analyze what products are performing well using data pre-processing, SQL & Machine Learning algorithms to inform how to improve management of inventory and sales. The aim of this project is to develop a retail analytics system for small/local retailers. The system will be simple and web based to provide insightful data to help improve the inefficiencies of inventory, improve predictions, increase efficiency, improve resource use and make informed decisions.**

**Keywords-: InsightCart, Artificial Intelligence, Retail Sales Intelligence, Data Analytics, Demand Forecasting, Inventory Management, Customer Behavior, Business Intelligence, Predictive Analytics, Interactive Dashboards.**

## I. INTRODUCTION

Data is becoming a very important factor in making informed decisions in the retail sector. However, many small/local retailers are struggling to understand how to analyze sales, manage inventory and understand customer trends. Traditional retail systems are focused on transactions and inventory with no predictive analytics or data Driven Decisions. This can make it difficult for retailers to understand sales trends, predict demand, optimize inventory and identify profit opportunities. [6], [7]

However, through the rapid development of AI, machine learning and data analytics it is now possible to create systems with AI capabilities for the retail industry. This can be achieved by taking raw data and making it insightful through various systems. This can also be achieved through manual systems using spreadsheets but can be time consuming and lacks features such as demand forecasting, customer behavior analysis and recommendations. [6], [7]

InsightCart is an AI powered Retail Sales Intelligence System. This project will aim to overcome this by creating an AI powered Retail Sales Intelligence System. This will help retailers analyze sales data, monitor inventory and make informed decisions through a web-based interface. The system will help analyze sales trends, product performance and provide insights around future demand through data analytics, interactive dashboards and AI.

The main aims of this work are to create a web-based Retail Intelligence System. This will help analyze sales and inventory through data analytics to understand sales trends, product performance and customer behaviour. This will help provide demand forecasting with data driven recommendations to help improve inventory management.

The system uses data processing, analytics, interactive visuals and AI to create a Retail Intelligence System for local retailers. This will help take raw data and make it insightful for local retailers to help improve processes, reduce inventory inefficiencies and make informed decisions regarding inventory, sales strategies and business growth.

## II. RELATED WORK

Traditionally there have been systems to help manage the retail business. These have been focused on transactions and billing. Whilst helpful they lacked features such as advanced sales analysis, demand forecasting and data Driven Decisions. Many small/local retailers still use spreadsheet and manual systems to make it difficult to understand sales trends and maximize inventory. However, with the rise of data analytics and Business Intelligence (BI) people have thought about how to use data to research and create data driven systems to analyze retail performance. Traditional analytics can be used to track sales history and KPIs however tend to give descriptive analysis instead of predictive recommendations. [6], [7]

Recently there has been an increase in AI driven insights being used for Retail Intelligence Systems. This has been focused on demand forecasting, customer behavior, product recommendations and inventory optimization. Machine learning can be used to analyze sales history to predict future demand. Data can be made more readable using data visualization but can be challenging for small retailers due to the complexity and cost of advanced analytics software. [1]-[4]

Modern Retail Intelligence systems use data processing, statistical analysis, machine learning and interactive data visualization to help with decision making. However, it is an opportunity to create a system that contains all these features and is easily accessible for local retailers. This project will aim to overcome this by creating an AI driven Retail Sales Intelligence System. This will provide local retailers with a single application to help analyze retail sales, manage inventory,

predict demand and provide business insights. The system uses data pre-processing, SQL, interactive dashboards and machine learning (where applicable) to analyze sales trends, product performance, customer behavior and help with inventory planning. The goal of this project is to make retail analytics easier for local businesses to understand. This will help turn raw transaction data into insightful information to improve efficiency. [2], [3], [6]

## III. DATA ACQUISITION & PREPROCESSING

**Data Collection**- The InsightCart retail system will take retail sales and inventory data to provide insights on business performance. This can be done using public retail data, sample POS transaction data or given historical sales data. This will contain transactional information including Transaction ID, Transaction Date, Product ID, Product Category, Quantity Sold, Unit Price, Revenue & Inventory Levels. Where possible customer data will be included to help understand customer behavior and sales trends. This data can be used to analyze sales trends, product performance, product flow and create demand predictions. If real data cannot be obtained from a retail scenario this can be demonstrated through sample data. This will be in a structured format to provide analysis capabilities.

**Data Extraction & Feature Engineering**-The retail data will go through a clear pre-processing stage to ensure high quality and consistent data. This will start by importing the data from CSVs or databases to understand the data. This will include data types, missing data & duplicate records. The following will be done. [6], [8]

The data will be cleaned to remove any missing data, duplicate transactions, inconsistencies and invalid data. The data will be transformed to ensure all dates, product categories, quantity, price and sales are consistent. New features will be created using feature engineering to provide information such as total sales revenue, daily sales, monthly sales, average transaction value & product performance. Any outliers will be identified to understand if any data is unusually high or low. This will help understand if this is due to incorrect data entry or special transactions. The data will be aggregated to provide a summary of transaction data per product, category, date etc. This will help with business intelligence and dashboards. Finally feature selection will be applied to understand the most important variables for analyzing sales data, customer behavior, inventory & demand. [6], [8]

To understand seasonal trends and predict future demand, historic sales data can be analyzed. This can be done by turning the data into time-based values. Numerical features will be scaled depending on the machine learning algorithm. Categorical values will be converted to numerical values. [2], [3]

The data will then be split into training & testing data to help understand how well the demand forecasting model will perform. If the sales are time dependent it is best to split the data in chronological order to prevent data leakage. The processed data will then be input into InsightCart to provide interactive dashboards, sales reports, inventory analysis & business insights. [2]

### 3.1 System Architecture

- **Data Processing**: Data will be taken from CSV files, databases or POS. This data includes transaction data, product data, amount sold, price, revenue and inventory data. Data will be then input into the application.
- **Data Preprocessing**: Data will be cleaned to give clean data of high quality. Any missing data, duplicates, wrongly entered data and irregularities will be removed. Features of interest include total revenue, monthly sales, average sale value and product performance
- **Feature Engineering & Analytics**: Features will be identified. By using SQL and analysis, insights regarding sales trends can be found. From this we can see how well our products are selling, what products customers are purchasing and trends in inventory. These can give us insights. [6], [7]
- **AI & Demand Forecasting**: Using data from the AI section, we can forecast what demand there will be for certain products. By analyzing historical sales data using machine learning techniques, we can predict demand for products. We can suggest product performances and when to top up inventories. A model to forecast product demand will be made and trained using historical sales data. Accuracy of this model will be measured. [1]-[4]
- **Dashboard & Visualization**: The results will be presented in an interactive web dashboard. This will help local retailers understand how they are doing. Charts will be shown for sales, summaries for revenue, product comparisons, inventory indicators and demand forecasting. KPIs will be used.
- **Insights**: Valuable insights will be gained from the system. This will help local retailers understand which products are performing well, sales trends, products with low inventory and sales forecasts. This will be displayed using cards, charts, tables and recommendations.

We can extract valuable insights from raw retail data by having multiple layers to this system. This can be done through preprocessing, analyzing, forecasting using AI and visualizing through interactive data. This will help to improve sales monitoring, inventory planning and decision making. [6], [7]

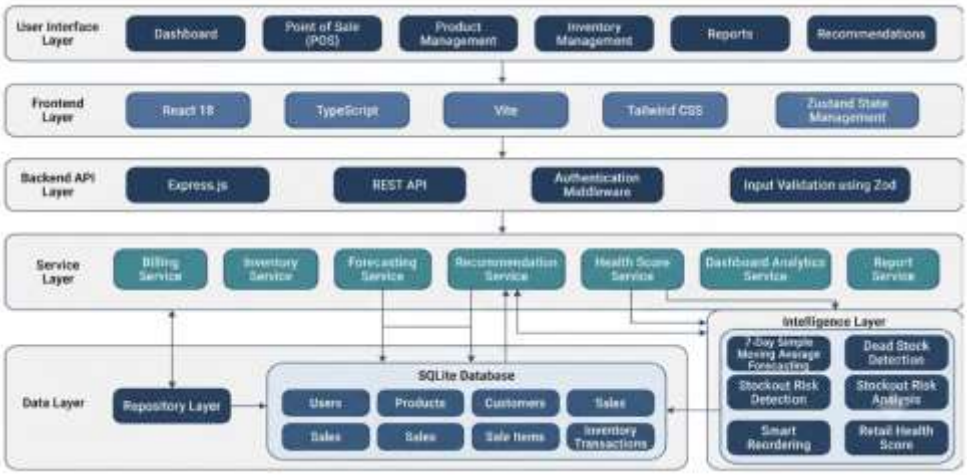

**Figure 1: InsightCart System Architecture**

## IV. MACHINE LEARNING

The InsightCart AI driven retail sales intelligence model makes use of data analytics and machine learning algorithms to analyze historical retail data. This will help understand sales trends to help with demand forecasting. Many factors such as seasonality, popular products, customer behaviors and previous sales can affect sales in retail. Historical sales data can be used to predict future sales of a product. This would be done by organizing the data into a time series. Based on the data available a model will be selected. Predictions can be used to help with inventory planning and decision making. Machine Learning can be used to gain insights into patterns that are hard to find manually. [1]-[4]

By using machine learning, many benefits can be achieved. Demand Prediction: predict demand for products based on historical sales. Sales Trends: Understand sales trends, increases/ decreases and seasonal trends. Product Performance:

Understand which products are performing well/poorly. Inventory Optimization: Suggest when to top up stocks within inventories. Data Driven: Generate meaningful insights from historical and current retail data.

**Model Training & Evaluation:** The forecasting demand model will be trained using clean and engineered data from historical sales data. This may include dates of transactions, previous sales quantity, product category and seasonality. The model will look at different categories of products, seasonality and other indicators to identify future demand for products. The model will be created by preprocessing the data. This includes cleaning and transforming the historical sales data. Features will then be engineered to produce time based and sales related features. The data will then be split into two parts (training and testing) in chronological order. The model will use historical sales observations to train. The model will then be evaluated using appropriate measures of accuracy such as Mean Absolute Error (MAE), Root Mean Squared Error (RMSE) and Mean Absolute Percentage Error (MAPE). The demand forecast and relevant insights will be shown on the InsightCart dashboard. It is more important for the model to perform well on unseen data to show how well it predicts future demand. This can help local retailers make informed, accurate and efficient decisions about buying. [2], [3], [4]

## V. IMPLEMENTATION

The InsightCart system will be a web-based application to help provide data processing, retail analytics, machine learning and interactive data visualization to help make data Driven Decisions.

- **Tools & Frameworks**: The system can be created using many tools. Python can be used to help with data processing, analytics and machine learning. NumPy and Pandas can be used to clean, transform, calculate numeric values and engineer features. SQL or DBMS can be used to store, search, filter and aggregate retail transaction and inventory data. Scikit-learn can be used to preprocess data, machine learning and model evaluation. Matplotlab, Seaborn and Plotly can be used to visualize data. Flask can be used to create the backend APIs. HTML, CSS and JavaScript can be used to create the front end. Jupiter Notebooks or Google COLAB can be used to explore the data. [6]
- **Data Processing & Analytics**: Processing of data will create meaningful insights. Data Input: Sales and inventory data from retail stores will be input from CSV, databases and POS systems. Data Cleaning: Handle missing data, identify and remove duplicate data. Uniform data. Feature Engineering: Calculate total revenue from sales, monthly sales and product performance. Data Storage: Data will be stored in a database. Sales Analysis: Insights into sales trends, patterns and product performances can be gained by running SQL queries. Forecasting Demand: Estimate demand.
- **Insights**: Results will be summarized and recommendations for inventory will be made. Dashboard: Key performance indicators, graphs, reports and forecasting can be viewed in an interactive web dashboard.
- **Analytics & Recommendations**:
  Rules/validations will be applied to gain meaningful insights. Sales data will be calculated based on processed transaction data. Demand forecasting will be calculated based on chosen models. Sales Analysis: Popular products, trends within sales and changes in sales can be observed. Inventory Monitoring: Products with low stock quantities can be identified. Demand Forecasting: Future sales can be estimated from historical data. Insights: Results will be summarized. Validity: Data will be checked for accuracy and consistency. Any missing data will be identified. [1], [2], [6], [7]
- **Deployment**: The system will be a web-based application. Depending on the technologies used this can be deployed locally on a computer, deployed onto a suitable cloud platform or can be accessed using supported browsers on Windows, MacOS and Linux. This provides a scalable and modular system to analyze retail data, forecast demand and provide business intelligence. The aim of the system is to provide local retailers with advanced retail analytics insights in an easy-to-use format. This will help them understand how they are performing and make data Driven Decisions.

## VI. RESULT & PERFORMANCE

**Model Evaluation:** The performance of the InsightCart: AI Powered Retail Sales Intelligence System can be measured by looking at how accurate the sales analytics are, how much error there is in the demand forecasting, how long it takes to process data and how fast the dashboard is. The system will help turn transaction data from retail into meaningful insights to help with planning of inventory. [2], [3]

Table 1: Performance Evaluation Metrics

| Metric | Full Form | Purpose |
|---|---|---|
| MAE | Mean Absolute Error | Measures average forecasting error |
| RMSE | Root Mean Squared Error | Measures forecasting error with greater penalty for large errors |
| MAPE | Mean Absolute Percentage Error | Measures forecasting error in percentage terms |
| Processing Time | Data Processing Time | Measures time required to process data |
| Response Time | Dashboard Response Time | Measures dashboard responsiveness |

The system can be measured in terms of Mean Absolute Error (MAE): How much error there is on average between actual and forecasted sales. Root Mean Squared Error (RMSE): Error in the forecasting. Larger errors penalized. Mean Absolute Percentage Error (MAPE): Error in forecasting as a percentage. Actual values should be appropriate for percentage. Sales Analysis: Ensure the sales have been calculated with accuracy. Data Processing Time: How long it takes to process retail data. Dashboard Response Time: How quickly reports are loaded. [2], [3]

The system can be measured using historical data for products, Quantity Sold and retailer transaction data. The accuracy of the demand forecasting should be measured using data further down the chronological order which was not used in the forecasting. The calculations used in the analytics should be measured against verified data. [2]

**Sales Analytics & Forecasting**: Sales trends, product performance and inventory monitoring can be used to analyze this system. When the forecast results have been compared to actual sales, it can be seen how well the model has predicted the sales values. The InsightCart system will be tested in order to ensure accuracy, reliability and effectiveness. Sales Trends: Ensure daily, monthly and product sales trends can be accurately identified. Product Performance: Ensure products with high and low performance can be identified. Inventory Monitoring: Check that the low stock alert is accurate by comparing to inventory data and threshold values. Demand Forecasting: Actual sales values will be compared to the forecasted values. By using appropriate error calculations, accuracy of the model prediction can be measured. Dashboard Visualizations: Charts, KPI's and reports in the dashboard are accurate and insightful.

**1. Functionality, Efficiency & Stress Testing**

Volume of Data: See how the system operates with varying volumes of data. Repetitiveness: Process data and generate reports multiple times. Dashboard Speed: How quickly analysis reports, charts and visualizations can be generated. Data Accuracy: Ensure information displayed is accurate. Error Tolerance: See how the system handles errors such as missing data, incorrect data and unsupported files.

This can highlight any issues with efficiency of the application. It will make sure the application is robust, responsive and reliable. From testing InsightCart, insights can be gained on how accurate it is at analyzing retail data to provide business insights. Quantitative results should be given.

## VII. DISCUSSION

The InsightCart: AI-Powered Retail Sales Intelligence System aims to bring together different aspects of retail data to give local retailers an overview of their business. By analyzing the data using data pre-processing, SQL, ML and dashboards local retailers can make improvements to their business. Compared to traditional retail management systems which mainly focus on transactional, billing and inventory data, InsightCart focuses on providing insights from previous retail data. Benefits of InsightCart include Data Driven Decision Making, taking raw transactional data and providing useful business insights. Sales Performance Analysis, identifying high performing products and looking at sales performance. Demand Forecasting, predicting product demand based on sales history. Inventory Management, identifying any potential stock shortages. Interactive Visualization, providing a dashboard, charts and KPIs to visualize complex retail data. Accessibility, providing an online system to easily provide retail analytics to local businesses. However, the effectiveness of InsightCart will depend on the quality of data provided, choice of analytical tools, forecasting model and amount of historical data available. [1]-[3], [6], [7]

A reliable way to analyze InsightCart can be used to see if it can improve demand forecasting, reporting and inventory planning. Improvements can be made to InsightCart to make it more advanced. These improvements include Advanced Demand Forecasting, by using advanced ML and time series models to identify seasonal trends, changing demand and product specific sales. Customer Segmentation & Personalization, by using clustering and recommendation algorithms to identify customer segments and their purchasing preferences. If enough customer data is available tailored product recommendations

can be provided. Real Time Inventory Monitoring, by linking to POS systems and inventory databases to monitor stock levels. Alerts can be set up for low stock to help with ordering. External Factors, by adding in relevant factors such as holidays, promotions and seasonal trends. If reliable external data is available this can be used. Cloud & Mobile: by implementing this to provide scalability for a multi store retailer. A mobile friendly dashboard can be used so retailers can easily access the app. Business Recommendations: recommendations can be made from the analytical results. This can help with inventory planning, choosing the right products and increasing sales. [1]-[4]
These improvements can help make InsightCart a more all-in-one retail intelligence solution to help local merchants.

## VIII. CONCLUSION

The InsightCart is an AI-Powered Retail Sales Intelligence System proposed in this research project to help companies in the retail industry. By using data analysis, sales performance, inventory analysis and forecasting the proposed system can provide useful insights from retail data. InsightCart aims to help local retailers understand their customers purchasing trends, product performance, track inventory and predict product demand. The web based interface will make it easier to access retail analytics. The performance of the system will depend on the quality of data, models and validation performed on the relevant data sets. Future work will focus on improving demand forecasting by using advanced ML algorithms and time series models to improve accuracy. Real time sales and inventory analytics by using POS systems. Customer segmentation and personalization can be added to improve understanding of customer preferences. External factors such as seasonal trends, holidays and promotions. Deploying the application onto cloud systems to improve scalability, ease of access and performance A mobile friendly interface can be used so retailers can easily view sales analytics and inventory. The system can be tested using real data and performance. InsightCart is a scalable and easy to use retail intelligence solution that can help local retailers make informed decisions, optimize stock, understand their sales performance and improve efficiency.
The proposed system will provide a good foundation to an intelligent and efficient retail management system using analytical features and an easy-to-use web interface.
